Abstract

A brief geologic reconnaissance and geochemical survey of molybdenum mineralization near Schiestler Peak, Sublette County, Wyo., indicates that molybdenite occurs in this area as disseminations and blebs in granitic or quartz monzonitic rocks intruded by felsic dikes of similar composition. Samples of stream sediments, panned concentrates from stream sediments, soils, rocks, and water were collected in the geochemical survey. Analytical results show that in reconnaissance, panned concentrates are the best of the sample types used in this study to detect molybdenum mineralization. More detailed analysis of the distribution of the molybdenum is best achieved through the collection of rock samples. Hydrothermal alteration is generally not conspicuous in the study area; however, rock samples that contain molybdenite are usually slightly enriched in silver, copper, lead, and in several instances, gold. Conversely, there appear to be negative associations between molybdenum and zinc and between molybdenum and several of the rare-earth elements. Mo concentrations in the rock samples with no visible molybdenite range from undetectable at a sensitivity of 5 parts per million (ppm) to 700 ppm. Mo content in rock samples containing visible molybdenite ranges from 10 ppm to greater than 2,000 ppm. Stream-sediment values range from undetected to 15 ppm; panned concentrates from undetected to 15 ppm; soils from undetected to 20 ppm. Analyses of the water samples indicate Mo concentrations from 0.8 parts per billion (ppb) to 4.8 ppb. As currently understood, this deposit is not extensive or continuous, but drilling to provide information on the vertical extent of mineralization may alter this opinion.

Introduction

The purpose of this report is to present the results of a brief geologic reconnaissance and geochemical survey of molybdenum mineralization near Schiestler Peak, Sublette County, Wyo. This study was made at the request of the U.S. Forest Service to assist that agency in making land-use decisions. A more detailed study of the occurrence is being made in the form of an M.S. thesis by Jon Benedict of the University of Wyoming in connection with a mineral resources appraisal by the U.S. Geological Survey of the Bridger Wilderness.

No geologic report of the molybdenum deposits has ever been published although the deposits have been known since the 1930's (or earlier) when several 20-pound (10 kg) specimens were brought to the First National Bank in Lander, Wyo., by a prospector seeking capital. Those spectacular specimens consisted of molybdenite sheets in a quartz and feldspar matrix. The only previous geologic study was done by W. H. Wilson of the Wyoming Geological Survey who spent three days of reconnaissance in 1953 and prepared a brief, unpublished report in 1955, which included one analysis. U.S. Forest Service personnel from the headquarters of the Bridger-Teton National Forest in Jackson, Wyo., have collected an extensive file of correspondence and photographs relating to the mineralization but have no geologic reports of value.

Prospecting, staking, overstaking, and promoting of various types have been pursued by several individuals and companies in the area from the 1940's to 1980. Serious efforts of exploration and sampling were begun in 1963; a

road was built and heavy mill machinery was brought to the southwest side of Schiestler Peak (Plate 1). Because the deposits are in the Bridger Wilderness, there has been considerable opposition to any development. In 1979, the mining claims were owned by Timberline Minerals, Inc., Dubois, Wyo., who had leased the claims to Koppen Mining Company, Albuquerque, N. Mex. Koppen Mining was engaged in exploratory activity on the claims at the time of our work.

Acknowledgments

We are especially indebted to Mr. Al Reuter and other members of the U.S. Forest Service who assisted us in every way possible with this preliminary effort, including the use of a helicopter to provide access to the area. We gratefully acknowledge the cooperation of Koppen Mining Company in connection with our work.

Location

The attached map (Plate 1) (at back of report) shows the general geology and the geography of the area. The previous mining activity has taken place on the west, southwest, and south sides of Schiestler Peak with several other small prospects scattered about the general vicinity. The mineralization occurs in the northern half of the Temple Peak 7 1/2-minute quadrangle near and above timberline at elevations from about 9,700 feet to 11,200 feet above sea level. Access to the mining claims on Schiestler Peak is via an unimproved dirt road through a locked gate several miles to the southwest at Big Sandy Opening, one of the principal gateways to the Bridger Wilderness. Big Sandy Opening lies between Boulder, Wyo., and South Pass near the southern end of the Wind River Range and can be reached by dirt road from Boulder, from the old Oregon Trail road east of Farson, Wyo., or from a dirt road leading east from U.S. Highway 187 between Farson and Boulder. Access to other molybdenite occurrences in the area is only by foot.

General Geology

All the bedrock in the Schiestler Peak area is thought to be Precambrian in age, based on the general geology and appearance of the rocks throughout the extent of the Wind River Range. No evidence, regionally or locally, has been found to suggest Laramide or younger igneous activity in the Wind River Range. Rocks collected for age dating in the vicinity of the mineralized rocks have not yet been analyzed.

The Precambrian geology in the Schiestler Peak area (Plate 1) is dominated by two phases of a batholithic complex, an older diorite phase, and a younger granitic or quartz monzonitic phase. This batholith crops out throughout much of the southern Wind River Range and is bounded by Archaean gneisses on both its northern and southern margins. The southern gneiss (outside map area) is found within 6.4 km (4 mi) of Schiestler Peak and has definite sedimentary characteristics. The northern gneiss (north of map area) is more felsic than the southern gneiss, and could be of either igneous or sedimentary origin.

The quartz diorite phase of the batholith is the oldest rock cropping out in the study area. This phase is uniform in both composition and appearance throughout its extent. It is a medium-grained, equigranular rock with slight

to moderate foliation and a "salt and pepper" appearance. It is found structurally beneath the younger phase of the batholith in many places cropping out along valleys and in cirque bottoms.

The younger granitic or quartz monzonitic phase covers about two-thirds of the study area. It is variable in both composition and appearance, ranging from equigranular granitic to porphyritic quartz dioritic (with microcline phenocrysts) to an interlayering of these two types. Discontinuous felsic dikes and(or) inclusions of similar composition are concentrated in zones within this unit but with no general trend. Molybdenum mineralization is restricted to this younger phase of the batholith.

The two phases of the Precambrian batholith are spatially associated across a transitional contact which parallels the foliation of the adjacent rock. This contact is a zone made up of an intermixture of both phases through a width of from 10 to 500 meters. The contact zone is roughly planar, paralleling a plane whose strike is N. 25° W. and dip is 35° NE., consistent with the dominant direction of foliation.

Two types of mafic intrusions crosscut the area. These are represented by fine-grained black dikes and grey-green dikes with porphyroblastic feldspars. The fine-grained black dikes are moderately continuous. They range from 10 centimeters to 4 meters in width and have no dominant trend. The porphyroblastic dikes range in width from 1 meter to 10 meters and generally trend N. 40° W. and dip 50° SW. Both types of dikes were intruded into the Precambrian country rock and are also thought to be of Precambrian age.

Structurally, the area is dominated by foliation which strikes N. 25° W. and dips 35° SW. This trend is defined both by mineral orientation of the batholithic rocks and by the trend of the contact between the two phases of the batholith. Fractures, joints, and shear zones in the area have no dominant azimuth, but generally dip along a nearly vertical plane. Chlorite and epidote are present in many of these structures. No mylonitization is found. Although silicification is rare within the study area, it is present in shear zones farther east.

Molybdenite Occurrences

The molybdenum mineralization occurs as molybdenite (MoS_2) disseminations and(or) blebs in the granite or quartz monzonite and was found in the country rock as well as in the felsic dikes or inclusions. In addition, MoS_2 was seen in quartz pegmatites and in quartz veinlets near shear zones.

The area was extensively glaciated and denuded of soil in Pleistocene time. The west-facing slopes of Schiestler Peak are comparatively gentle, but the north- and east-facing slopes are the headwalls of cirques and are vertical in places. In the past, many specimens of nearly pure molybdenite in granitic rock have been found in glacial debris in the area; thus, it is conceivable that the extant molybdenite deposits may be only a remnant of deposits which were at one time considerably larger.

Although the prospect pits exhibiting molybdenite on the southwest side of Schiestler Peak also contain marcasite, pyrite, and chalcopyrite, most other locations where molybdenite was seen display no macroscopically visible alteration or mineralization other than chlorite-epidote and occasional finely

disseminated pyrite. Moreover, there is no obvious relationship among the molybdenite occurrences except that they are found in a somewhat localized area and are of a similar deposit form. Rather, the MoS₂ seems to occur somewhat haphazardly within the study area in small, scattered, discontinuous zones.

The mafic dikes in the area are apparently unmineralized and the felsic dikes which, in some places, contain molybdenite, exhibit no general trend and do not parallel shear zones in the vicinity. In short, there is no obvious surficial evidence to suggest that the dikes are rooted to a hidden intrusive ore body.

Geochemical Sampling

To determine parameters for geochemical appraisal, samples were collected in the vicinities of known molybdenum occurrences using as media bedrock, soil, stream sediment, and heavy-mineral concentrates from stream sediments. A few water samples were collected from streams and springs for strictly reconnaissance purposes inasmuch as ground-water sample sites are scarce in the area. Nearly all stream drainages in the vicinity were sampled, and rock and soil sample sites were distributed in an area approximately two miles (3 km) in radius centered at the site of current exploration drilling being conducted by Koppen Mining Company on the southwest side of Schiestler Peak. Wherever rocks containing visible molybdenite were found, samples were collected and deliberately "high graded" to obtain a geochemical signature for the mineralization and should not, therefore, be considered as representative outcrop samples. Rocks exhibiting evidence of mineralization such as iron-oxide staining of disseminated sulfides were also preferentially collected wherever found. In addition, rock samples with no evidence of mineralization were collected to provide data to determine background abundances of elements.

Plate 2 shows the locations of the samples collected in the study area. Prefixes and suffixes have been deleted from the sample numbers for clarity.

Sample Preparation and Analysis

Rock samples were crushed, ground, split, and analyzed. Soil and stream-sediment samples were dried and sieved through an 80-mesh (177 micron) sieve and the minus-80-mesh fraction was analyzed. Panned concentrates were separated into magnetic and nonmagnetic fractions, examined for minerals present, and split for analysis. Water samples were collected in pairs--one raw and unfiltered for determination of pH and anion content and, at the same site, a second sample was filtered and acidified with nitric acid for analyses of Cu, Pb, Mo, and Zn concentrations. Six-step semiquantitative emission spectrographic analyses were made by R. T. Hopkins, Jr. of all the samples except the waters, using the method of Grimes and Marranzino (1968). Atomic-absorption analyses for Au, Ag, Cu, Pb, Zn, Sb, Cd, and Bi were made by W. L. Campbell using methods described by Ward and others (1969) and Viets and others (1979), in which the readily soluble portion of several elements is dissolved and analyzed. Water analyses were made by J. B. McHugh using methods described by Miller and Ficklin (1976). Mineralogical examination of the nonmagnetic fraction of the panned concentrates was conducted by R. B. Tripp. T. Hickey provided computer-generated statistical information.

Results

Tables 1, 3, 5, 8, 10, and 14 show the analytical values for the various sample types. In each case, only analyses of elements for which at least one sample shows a value at or above the detection limit are included. That is, elements which were undetected and(or) found below the measurable detection limit for all samples of a type were excluded from the tables. Table 2 shows the mineralogy of the nonmagnetic fraction of the panned concentrates and Table 7 shows the field descriptions of rock samples collected. Tables 4, 6, 9, and 11 show graphical illustrations of the distributions of the analytical values for the sample types. Tables 12 and 13 show the computer-generated statistical correlations between Mo and the other elements analyzed in the rock samples. To perform correlation analyses among the elements, the qualified analytical values, i.e., N - not detected at the limit of detection; L - detected, but below the limit of determination; and G - greater than the value shown, were replaced by 0.5 times the limit of detection, 0.7 times the limit of detection, and 1.5 times the value shown, respectively. These replacements facilitate the determination of possible negative correlations as well as positive associations among the data. In addition, the replacements help avoid the selective bias which may occur in using only unqualified data pairs to compute correlation coefficients. For example, any unqualified value for Mo may be considered to be anomalous in the samples analyzed; therefore using only sample data with unqualified values in correlation analyses for Mo necessarily selects only the samples which are mineralized. It may be argued that the replacement factors are unrealistic, but it should be pointed out that the correlation analyses are used in this case simply to provide suggestions of associations which may provide impetus for further, more detailed investigations. This is especially true in this instance inasmuch as the sampling coverage was, as previously indicated, quite selectively based. Tables 12A and 13A show the correlation coefficients using the analytical data in its original form and Tables 12B and 13B show correlations using the logarithms of the original data. The log-transformations tend to highlight associations in the data since many trace-element distributions are found to be at least approximately log-normal.

Discussion

At a confidence level of 95 percent, a correlation coefficient of absolute value greater than or equal to 0.53 implies significant association for the 12 selected rock samples in Table 13 and a coefficient of 0.22 or greater suggests meaningful correlation for the other 77 rock samples in Table 12 (Snedecor, 1946). Using these coefficients it can be seen from Tables 12 and 13 that Cu, Au, Ag, and Pb are elements which appear to be associated with Mo in a positive sense whereas Ca, Be, La, Sc, Y, and Zn coefficients seem to show significant negative correlation with Mo.

The rare earths are found in biotite, rutile, zircon, and monazite, and it is possible that these minerals have been altered in the area of mineralization as may be evidenced by the negative associations with Mo. The zinc values in the rock samples are all significantly lower than what might be expected in felsic igneous rocks in general (Hawkes and Webb, 1962). It is unclear whether this is a real effect of a chemical differentiation process in the area or a result of insolubility of the zinc minerals which would affect the atomic-absorption determinations. At any rate, the negative correlations between Mo and Zn and(or) the rare earths indicate that further

study along these lines might provide an aid to exploration in the area.

Because of their economic importance and apparently significant positive statistical associations with the molybdenum mineralization in the area, Au, Cu, Ag, and Pb have been selected along with Mo as the elements of greatest interest in this preliminary study. Plates 3 and 4 show Mo anomaly locations and sites of samples with anomalous Au, Cu, Ag, and Pb values, respectively. The thresholds for indicating geochemical anomalies were chosen as any analytical value at or above the detection limit for spectrographic determinations of Ag and Mo and any value at or above the detection limit for atomic-absorption determinations of Au. For Cu and Pb the thresholds were chosen as twice the mean of background values as suggested by Boyle (1971).

Analyses of the mineralized rocks show that Mo is accompanied by traces of Au in 7 of the 12 samples (Table 10). This suggests a significant Mo-Au association, which is also indicated in the correlation coefficients (Table 13). All four of the panned concentrate samples in which Au was detected (Table 1) were taken in drainages below Mo mineralization. Mo was also found in analyses of these concentrates. Analyses of panned concentrates that show either Mo or Au in other drainages should therefore be useful as prospecting guides elsewhere in the Wind River Mountains.

Even though only four water samples were collected, it can be seen that two of them are considerably higher in Mo content than the others (Table 14). These two samples, as located in Plate 2, are from ground water in the proximity of the molybdenum mining prospects in contrast to the samples much lower in Mo content that were collected at locations approximately two miles (3 km) from the mining activity. This suggests that water sampling may be a useful reconnaissance tool for detecting molybdenum mineralization in the area provided suitable sample sites are available.

From Plate 3 it can be seen that Mo anomalies in the stream sediments and panned concentrates ring the area of mineralization quite effectively. The concentrates show anomalies at greater distances from the known Mo occurrences and are, therefore, the best of the sample types used in this study in terms of reconnaissance exploration. The sediment samples more tightly encircle the mineralized vicinity and provide a somewhat more specific delineation of the area of interest. The results suggest, therefore, that a reconnaissance effort aimed at discovering molybdenum in this region is best served by using stream sediments and panned concentrates in tandem.

The soil samples were taken to give backup data for the rock samples and to provide information from locations where outcrops were not available. The anomalies indicated from the soil data suggest, however, that in most cases the rock samples provide greater sensitivity. Rock samples, upon examination of Plates 3 and 4, are seen to provide the greatest detail with regard to the distribution and intensity of the occurrences of mineralization.

Conclusions

Evidence of mineralization in the vicinity of Schiestler and Temple Peaks is restricted to several scattered occurrences of molybdenite except on the southwest side of Schiestler Peak where sulfides of iron and copper also occur. With the exception of the localized occurrences at these prospect

sites, the molybdenum mineralization in the area is not intense and is not widely disseminated in any continuous fashion. The anomalies found in the geochemical survey corroborate the field observations to this effect.

Examination of the plotted Mo anomalies shows that the stream-sediment panned-concentrate sampling approach neatly spotlights the general area of molybdenum mineralization in the area, thus providing an effective reconnaissance method of investigation. Collection and analysis of rock samples, on the other hand, provides more detailed information on the distribution of the molybdenum mineralization. Moreover, manipulation and study of the rock sample data has suggested other elemental associations with molybdenum which may be of further use in mineral resource exploration in this area.

PERCENT TABLE FOR VARIABLE 26 (AA-CD-P) BY LINEAR INTERPOLATION FROM FREQUENCY TABLE
 IF SELECTED PERCENTILES FALL WITHIN DATA EITHER ABOVE OR BELOW THE LIMITS OF DETECTION,
 THE DATA VALUE ON THE TABLE IS GIVEN AS 0.999991E 50

| SELECTED PERCENTILE | DATA VALUE | ANTI LOG OF VALUE |
|------------------------|---------------|-------------------|
| 50.00 | -0.472220E+00 | 0.337117E+00 |
| 75.00 | -0.263886E+00 | 0.544646E+00 |
| 90.00 | -0.833300E-01 | 0.825411E+00 |
| 95.00 | 0.416702E-01 | 0.110070E+01 |
| 99.00 | 0.100000E+36 | 0.100000E+36 |

Table 7.--Descriptions of Rock Samples

| Sample No. | Field Description |
|------------|--|
| TEM200R | Medium-textured quartz monzonite with sparsely disseminated pyrite. |
| TEM201R | 3-5" quartz pegmatite veinlet with sparsely disseminated pyrite. |
| TEM202R | Fairly coarse granite with sparsely disseminated pyrite. |
| TEM203R | Medium to fairly coarse granite float with MoS ₂ blebs. |
| TEM204R | 1' granite dike with disseminated MoS ₂ . |
| TEM205R | Fe-stained granite with MoS ₂ blebs and sparsely disseminated sulfides. |
| TEM206R | 1-1/2" Fe-stained quartz veinlet with possible finely disseminated pyrite. |
| TEM207R | Fe-stained granite with crystalline pyrite. |
| TEM209R | Granite with sparsely disseminated pyrite and slightly chloritized biotite. |
| TEM210R | Granite with sparse, finely disseminated pyrite and slightly chloritized biotite. |
| TEM212R | Granite with rusty zones containing pyrite or marcasite. |
| TEM213R | Fairly coarse granite. |
| TEM215R | Very felsic granite float containing 1" mafic veinlet. |
| TEM216R | 7' dike of fairly fine quartz monzonite. |
| TEM217R | Fairly coarse biotite-rich granite. |
| TEM218R | Fairly coarse, somewhat chloritized granite from minor shear zone. |
| TEM219R | Medium-textured granite. |
| TEM221R | 1/2" quartz pegmatite vein--rusty with small blebs and sparse disseminations of MoS ₂ . |
| TEM224R | Biotite-rich granite with moderate Fe-staining and augen gneiss texture. |
| TEM225R | Fairly fine granite with chloritized biotite and epidote fracture fillings. |
| TEM227R | Fairly coarse, moderately Fe-stained granite. |

Table 7.--Descriptions of Rock Samples--Continued

| Sample No. | Field Description |
|------------|---|
| TEM229R | 1-2' fairly fine-grained diabase dike. |
| TEM230R | Fairly coarse granodiorite float with MoS ₂ bleb. |
| TEM231R | Somewhat Fe-stained granite float with possible fine, sparsely disseminated pyrite. |
| TEM233R | Granite contact with chlorite-epidote schist from float. |
| TEM234R | Highly Fe-stained granite float. |
| TEM235R | Fairly coarse quartz monzonite float with disseminated pyrite and/or marcasite. |
| TEM236R | Fairly coarse diorite float containing sulfides. |
| TEM237R | Highly Fe-stained sulfide-rich granite float. |
| TEM241R | Highly Fe-stained, sulfide-rich gossan. |
| TEM242R | Quartz pegmatite vein. |
| TEM243R | Granite with slightly chloritized biotite. |
| TEM244R | Granodiorite float with weathered disseminated sulfides. |
| TEM247R | Quartz monzonite float containing MoS ₂ and disseminated pyrite. |
| TEM250R | Unmineralized, slightly gneissic granite. |
| TEM252R | Moderately Fe-stained granite with possible sparse disseminated sulfides. |
| TEM254R | Fairly fine granite with disseminated pyrite. |
| TEM256R | Fairly fine unmineralized granite. |
| TEM269R | Unmineralized granodiorite. |
| TEM270R | Granodiorite with disseminated magnetite. |
| TEM271R | 1/2" magnetite vein. |
| TEM272R | Granite with possible fine sulfides. |
| TEM273R | Fe-stained quartz pegmatite. |
| TEM275R | Fe-stained biotite-rich with hematite. |
| TEM277R | Magnetite(?) contacting biotite-rich granite from float. |

Table 7.--Descriptions of Rock Samples--Continued

| Sample No. | Field Description |
|------------|--|
| TEM279R | Fairly coarse, unmineralized granite. |
| TEM281R | 1' pegmatite vein with hematite. |
| TEM282R | Contact between fine and coarse granite from float. |
| TEM284R | Granite float. |
| TEM291R | Fe-stained granodiorite with chlorite, epidote, and disseminated sulfides. |
| TEM292R | Fe-stained, sulfide-rich granite float. |
| TEM294R | Fe-stained, sulfide-rich granite. |
| TEM295R | Chloritized granite with epidote fracture fillings. |
| TEM296R | Fe-stained, sulfide-rich granite float. |
| TEM302R | Quartz monzonite with sparse disseminated pyrite. |
| TEM304R | 15 X 20' quartz pegmatite inclusion with possible sparse fine MoS ₂ . |
| TEM305R | Highly Fe-stained quartz monzonite float with pyrite and magnetite? |
| TEM306R | Aplite float with sulfides. |
| TEM308R | Highly Fe-stained granitic gossan with scattered blebs of MoS ₂ . |
| TEM309R | Granodiorite with sparse, finely disseminated pyrite. |
| TEM311R | Fairly fine to coarse granite with MnO ₂ coating and disseminated pyrite. |
| TEM313R | Fairly coarse, unmineralized granite float. |
| TEM315R | 5" quartz pegmatite vein with hematite. |
| TEM317R | Slightly chloritized, fairly coarse granite. |
| TEM319R | Rusty red aplite contacting pegmatite. |
| TEM320R | Rusty red pegmatite contacting aplite. |
| TEM322R | Lightly Fe-stained granite. |
| TEM324R | Fairly coarse granite with minor hematite staining. |
| TEM325R | Slightly Fe-stained granite. |

Table 7.--Descriptions of Rock Samples--Continued

| Sample No. | Field Description |
|------------|---|
| TEM329R | 3-5" quartz pegmatite float. |
| TEM331R | 1-5" quartz pegmatite inclusion with magnetite? |
| TEM333R | Fe-stained, sulfide-rich granite float. |
| TEM334R | Fine-textured quartz monzonite float containing pyrite zones and a MoS ₂ bleb. |
| TEM336R | 4' quartz monzonite dike. |
| TEM338R | Rusty sulfide zone in quartz monzonite dike. |
| TEM339R | 8-10" quartz monzonite dike with sparsely disseminated pyrite. |
| TEM340R | Fe-stained, sulfide-rich granite float. |
| TEM342R | Fairly coarse, unmineralized granodiorite. |
| TEM343R | MoS ₂ -bearing pegmatite inclusion in granodiorite float. |
| TEM001R | Altered granite containing marcasite. |
| TEM002R | MoS ₂ -bearing granite. |
| TEM005R | Fine-textured quartz monzonite. |
| TEM006R | Coarse-grained granite. |
| TEM008R | Coarse-grained granite. |
| TEM009R | Altered quartz diorite dike. |
| TEM010R | Coarse-grained granite. |
| TEM018R | Biotite-rich granite. |
| TEM021R | Granite float containing MoS ₂ . |
| TEM022R | Mafic dike. |
| TEM004M | MoS ₂ -bearing granite specimen. |
| TEM007M | MoS ₂ -bearing granite specimen. |
| TEM303M | MoS ₂ -bearing quartz monzonite specimen with marcasite and pyrite. |
| TEM335M | MoS ₂ -bearing fine-grained quartz monzonite specimen from float. |
| TEM345M | Unmineralized granodiorite specimen from float. |

Table 7.--Descriptions of Rock Samples--Continued

| Sample No. | Field Description |
|------------|-------------------|
|------------|-------------------|

NOTE: TEM004M, 7M, 303M, 335M, 345M were withheld from quantitative analysis
as specimens for mineralogical inspection.

TABLE 8. --Analytical Values of Rock Samples Without Visible MoS₂

| Sample | Latitude | Longitude | S-Fix | S-Mg% | S-Ca% | S-Mn | S-Al | S-Ba | S-Be |
|----------|----------|-----------|-------|-------|-------|------|-------|-------|-------|
